SUMMATION IDENTITIES FOR REPRESENTATION OF CERTAIN REAL NUMBERS

GEORGE GROSSMAN, AKALU TEFERA, AND AKLILU ZELEKE

Received 27 March 2006; Accepted 28 March 2006

We present identities used to represent real numbers of the form $xu^m \pm yv^n$ for appropriately chosen real numbers $x, y, u, v$ and nonnegative integers $m$ and $n$. We present the proofs of the identities by applying Zeilberger’s algorithm.

1. Introduction

It is well known that every integer can be written as a sum of integral powers of 2. A somewhat related problem is to find for every positive integer $n$ a positive integer $k$ depending on $n$ with $k(n) < k(n + 1)$ and integer coefficients $a_i, i = 1, 2, \ldots, k - 1$, such that

$$n = \sum_{i=0}^{k-1} a_i 2^{2i}.$$  \hspace{1cm} (1.1)

The background and motivation for studying this problem lies in finding the zeros of the $j$th-order generalized Fibonacci polynomial defined by $F_j(x) = x^j - 1 - \cdots - x - 1$. Dubeau [1] and Flores [3] have shown that the positive roots of $F_j(x)$ are of the form $2 - O(2^{-j})$. Grossman and Narayan [4] have proven that the single negative zero of $F_j(x)$ has the form $-1 + O(j^{-1})$ for $j$ even and tends to $-1$ monotonically as $j \to \infty$. Using the fact that

$$F_j(x) = (x - 2 + \epsilon_j)(x + 1 - \delta_j)(x^{j-2} + a_{j-3}x^{j-3} + \cdots + a_1 x + a_0), \hspace{1cm} (1.2)$$

where $\delta_j$ and $\epsilon_j$ are positive, decreasing sequences for $j = 4, 6, \ldots$, Grossman and Zeleke [6] have found an explicit form for the coefficients $a_n$, where $i = 0, 1, \ldots, j - 3$, in terms of $\delta$ and $\epsilon$. The solution was found by solving a nonhomogeneous linear recurrence relation of the form $-a_n + b a_{n+1} + c a_{n+2} = 1$, where $b = \epsilon - 1 - \delta$, $c = (1 - \delta)(2 - \epsilon)$. As byproduct of this solution, several combinatorial identities were formulated by considering even- and odd-indexed terms of $a_n$.

Summation identities for real numbers representation

Some of these identities give representations of positive integers using binomial coefficients. Others are identities for representing certain types of real numbers. In this paper, we call these identities “real number identities.” Real number identities are interesting for various reasons. On one side, formulation and proofs of combinatorial identities traditionally have been linked to arguments that have their origin in counting problems. Such identities can then be used to represent positive integers. From this perspective, it is not obvious that one can formulate real number identities. This by itself makes the attempt to represent real numbers in terms of combinatorial identities interesting. Furthermore, by considering some special cases, we can use the real number identities to generate interesting sequences. We give five examples to demonstrate this fact. In the first example, we consider a representation of the integer sequence $2^n$, $n \geq 0$. What is different about this representation is that the summand in the identity involves irrational terms. In example two, we discuss an alternate way to generate the Fibonacci sequence $F_n$ with initial values $F_1 = F_2 = 1$. The third example shows how to generate a shifted even-indexed Fibonacci sequence $F_{2n+2}$, $n \geq 1$. The fourth example shows how to generate from Theorem 2.1 integer solutions of a Pell equation of the form $x^2 - 3y^2 = 1$. In example five, we give an identity that can be used to represent a certain type of rational numbers.

The real number identities in this paper have been introduced in [6] where the methods of proofs involve induction, previously known combinatorial identities, and algebraic manipulations. The goal of this paper is to present computer-generated proofs using Zeilberger’s algorithm. For a superb exposition of Zeilberger’s algorithm see, among others, the books $A = B$ [8] and Hypergeometric Summation [7] which are devoted to this and other methods. The paper is organized as follows. In Section 2 we present several real number identities. Computer-generated proofs of these identities are presented in Section 3. Throughout this paper, we denote the set \( \{k, k+1, k+2, \ldots \} \) for $k \in \mathbb{Z}$ by $\mathbb{N}_k$.

2. Main theorems

Theorem 2.1. For $n \in \mathbb{N}_0$, $b \in \mathbb{R} \setminus \{-2, -1\}$,

\[
\frac{1}{(b+1)^{n+2}} \sum_{k=0}^{n} \frac{b^{2k+1}}{(b+1)^k} \left( \frac{n+k+1}{2k+1} \right) = \frac{1}{b+2} \left( 1 - \frac{1}{(b+1)^{2(n+1)}} \right). \tag{2.1}
\]

Theorem 2.2. Let $n \in \mathbb{N}_1$ and let $b, c \in \mathbb{R} \setminus \{0\}$ such that $b^2 + 4c > 0$. Then

\[
\sum_{k=1}^{n} \frac{1}{2^n b^2} \left( \frac{b}{2c} \right)^{2n} \left( 1 + \frac{4c}{b^2} \right)^{k-1} \left( \frac{2n}{2k-1} \right) = \frac{\alpha \beta}{\alpha - \beta} (\alpha^n - \beta^n), \tag{2.2}
\]

where $\alpha = 1/(b^2 + 2c - \sqrt{b^2(b^2 + 4c)})$ and $\beta = 1/(b^2 + 2c + \sqrt{b^2(b^2 + 4c)})$.

Theorem 2.3. For $n \in \mathbb{N}_{-1}$, $b \in \mathbb{R} \setminus \{-2, -1\}$,

\[
\sum_{k=0}^{n+1} \frac{b^{2k}}{(b+1)^{n+k+1}} \left( \frac{n+k+1}{2k} \right) = \frac{b+1}{b+2} \left( 1 + \frac{1}{(b+1)^{2n+3}} \right). \tag{2.3}
\]
Theorem 2.4. Let $n \in \mathbb{N}_1$ and let $b, c \in \mathbb{R}$ such that $b \neq 0$ and $c > 0$. Then

$$\sum_{k=0}^{n} \left( \frac{b}{2^{n-k}} \right)^{2n+1} \left( \frac{b}{2c} \right)^{2k+1} \left( 1 + \frac{4c}{b^2} \right)^{k+1} \left( \frac{2n+1}{2k+1} \right) = \frac{\sqrt{\alpha} + \sqrt{\beta}}{\sqrt{\alpha \beta}} \left( \beta^{n+1/2} - \alpha^{n+1/2} \right),$$

(2.4)

where $\alpha = 1/(b^2 + 2c - \sqrt{b^2(b^2 + 4c)})$ and $\beta = 1/(b^2 + 2c + \sqrt{b^2(b^2 + 4c)})$.

Theorem 2.5. For $n \in \mathbb{N}_1$, $b \in \mathbb{R}\{ -2, -1 \}$,

$$\sum_{k=0}^{n-1} \sum_{m=2k+2}^{n+1+k} \frac{b^m}{(b+1)^{n+k+1}} \binom{n+k+1}{m} = \frac{b(n+1)}{b+2} - \frac{(b+1)^2}{(b+2)^2} \left( 1 - \frac{1}{(b+1)^{2n+2}} \right).$$

(2.5)

Remark 2.6. By substituting specific values for the parameters in the above theorems, one can get interesting identities. We consider five examples.

Example 2.7 (identities for $2^n$). By substituting $b = -1 + \sqrt{2}/2$ in Theorem 2.1, we get the following identity for the integer sequence $2^n$:

$$\frac{1}{2} + \frac{2^{n/2}}{2} \sum_{k=0}^{n} \left( \frac{3}{\sqrt{2}} - 2 \right)^k \binom{n+k+1}{2k+1} = 2^n.$$

(2.6)

If we let $b = -1 - \sqrt{2}/2$, we get a different identity for the sequence $2^n$:

$$\frac{1}{2} + \frac{2^{n/2}}{2} \sum_{k=0}^{n} (-1)^{n+k} \left( \frac{3}{\sqrt{2}} + 2 \right)^k \binom{n+k+1}{2k+1} = 2^n.$$

(2.7)

These two identities are different from other representations of $2^n$ in the sense that they involve irrational terms to generate an integer sequence. They are also interesting from this perspective.

Example 2.8 (generating the Fibonacci sequence.). In Theorem 2.2, choose $c = \pm 1/2$ and $b = \pm \sqrt{(\sqrt{5} - 2)/2}$. This makes $\alpha = (\sqrt{5} + 1)/2$ and $\beta = (\sqrt{5} - 1)/2$. Note that since $\alpha \beta = \alpha - \beta = 1$, the right-hand side of Theorem 2.2 is the sequence

$$G_n = \left( \frac{\sqrt{5} + 1}{2} \right)^n - \left( \frac{\sqrt{5} - 1}{2} \right)^n, \quad n \geq 1.$$

(2.8)

By setting $F_0 = G_0 = 0$, we get the following relation between $G_n$ and $F_n$ for $n \geq 0$:

$$G_{2n} = \sqrt{5} F_{2n}, \quad G_{2n+1} = F_{2n} + F_{2n+2}.$$

(2.9)

From this relation, we see that Theorem 2.2 provides a combinatorial identity to generate the Fibonacci sequence.
Example 2.9 (generating a shifted even-indexed Fibonacci sequence). In Theorem 2.1, if we let \( b = (1 \pm \sqrt{5})/2 \), then \( b^2/(b + 1) = 1 \) and Theorem 2.1 takes the form

\[
\sum_{k=0}^{n} \left( \frac{n + k + 1}{2k + 1} \right) = \left( \frac{5 + 3 \sqrt{5}}{10} \right)^n \left( \frac{3 + \sqrt{5}}{2} \right) + \left( \frac{5 - 3 \sqrt{5}}{10} \right)^n \left( \frac{3 - \sqrt{5}}{2} \right). \tag{2.10}
\]

One can show that the right-hand side of (2.10) is \( F_{2n+2} \).

Example 2.10. By substituting \( b = 1 \pm \sqrt{3} \) in Theorem 2.1, we get the following identity that generates the sequence \( a_0 = 1, a_1 = 4, \) and \( a_{n+2} = 4a_{n+1} - a_n \) for \( n \geq 0 \):

\[
\sum_{k=0}^{n} 2^k \left( \frac{n + k + 1}{2k + 1} \right) = \left( \frac{1}{2} + \frac{\sqrt{3}}{3} \right) (2 + \sqrt{3})^n + \left( \frac{1}{2} - \frac{\sqrt{3}}{3} \right) (2 - \sqrt{3})^n. \tag{2.11}
\]

The first few terms of the sequence \( a_n \) are 1, 4, 15, 56, 209, 780, .... One interesting property of these terms is that \( 3a_n^2 + 1 \) is a perfect square.

Example 2.11. By substituting \( b = 1 \) in Theorem 2.1 and \( b = -1, c = 2 \) in Theorem 2.2, we get the identities discovered in [6] for real numbers of the form \((1/6)(1 - 1/4^n)\).

3. Proofs of the theorems

Proof of Theorem 2.1. Since \( \binom{n+k+1}{2k+1} = 0 \) for \( k > n + 1 \) and \( k < 0 \), the identity in Theorem 2.1 can be rewritten as

\[
\frac{1}{(b + 1)^{n+2}} \sum_{k \in \mathbb{Z}} b^{2k+1} \frac{n + k + 1}{(b + 1)^k \left( \frac{n + k + 1}{2k + 1} \right)} = \frac{1}{b + 2} \left( 1 - \frac{1}{(b + 1)^{2(n+1)}} \right). \tag{3.1}
\]

This is also equivalent to

\[
\sum_{k \in \mathbb{Z}} \frac{(2 + b)b^{2k+1}}{(b + 1)^{k-n}} \left( \frac{n + k + 1}{2k + 1} \right) = (1 + b)^{2(n+1)} - 1. \tag{3.2}
\]

Let us denote the left-hand side of (3.2) by \( S_b(n) \). Let \( F_b(n,k) \) denote the summand of \( S_b(n) \), that is,

\[
F_b(n,k) = \frac{(2 + b)b^{2k+1}}{(b + 1)^{k-n}} \left( \frac{n + k + 1}{2k + 1} \right). \tag{3.3}
\]

Then \( F_b \) satisfies the recurrence equation (the recurrence equation is automatically generated by the Maple package ekhad which is available (for free) from http://www.math.rutgers.edu/~zeilberg)/:

\[
-(b + 1)^2 F_b(n,k) + (b^2 + 2b + 2)F_b(n+1,k) - F_b(n+2,k) = G_b(n,k+1) - G_b(n,k),
\]

where \( G_b(n,k) = (2 + b)b^{2k+1}(b + 1)^{n-k+2} \left( \frac{n + k + 1}{2k - 1} \right) \). \tag{3.4}
By summing both sides of (3.4) with respect to $k$, we get

\[-(b + 1)^2S_b(n) + (b^2 + 2b + 2)S_b(n + 1) - S_b(n + 2) = 0.\] (3.5)

Moreover, $S_b(0) = (b + 1)^2 - 1$ and $S_b(1) = (1 + b)^4 - 1$. Also $(1 + b)^{2(n+1)} - 1$ satisfies (3.5), and hence $S_b(n) = (1 + b)^{2(n+1)} - 1$. \(\square\)

Remarks 3.1. (1) In the sequel, we will use the same proof style. Compute a recurrence relation of order $d$ for the summand and sum the summand recurrence with respect to the summation index to get a recurrence for the sum $S(n)$. Check that the right-hand side also satisfies the same recurrence and that it agrees with $S(n)$ for the first $d$ initial values of $n$. Then the identity follows.

(2) We would like to note that one can also get the right-hand side of (3.2) by directly solving the recurrence (3.5) which has constant coefficients. For more details, see for instance [8, 9].

To make the proofs more compact, we introduce the following operator notations.

Definition 3.2. Given a function $F(n,k)$ of the (discrete) variables $n$ and $k$, define the forward shift operator $E_n$ by $E_nF(n,k) = F(n+1,k)$.

With this notation, (3.4) becomes

\[(-(b + 1)^2 + (b^2 + 2b + 2)E_n - E_n^2)F_b(n,k) = G_b(n,k+1) - G_b(n,k).\] (3.6)

From the proof of Theorem 2.1, we observe that to certify the truth of the identity, it would suffice to display the pair $(P,G_b)$ (called a “Z-pair”), where $P = -(b + 1)^2 + (b^2 + 2b + 2)E_n - E_n^2$.

In the sequel for a given function $F(n,k)$, a Z-pair $(P,G)$ means that $PF(n,k) = G(n,k + 1) - G(n,k)$. Since the Z-pair actually certifies the truth of the identity, it is called the proof certificate. Therefore, in the proofs of Theorems 2.2, 2.4, we only give the proof certificates.

Proof of Theorem 2.2. Since $\binom{2n}{2k-1} = 0$ for $k > n$ and $k < 1$, the identity in Theorem 2.2 can be rewritten as

\[
\sum_{k \in \mathbb{Z}} \frac{1}{2^nb^2} \left( \frac{b}{2c} \right)^{2n} \left( 1 + \frac{4c}{b^2} \right)^{k-1} \binom{2n}{2k-1} = \frac{\alpha^n - \beta^n}{\alpha\beta(\alpha - \beta)}. \] (3.7)

Let us denote the summand of the left-hand side of (3.7) by $F_{b,c}(n,k)$, that is,

\[F_{b,c}(n,k) = \frac{1}{2^nb^2} \left( \frac{b}{2c} \right)^{2n} \left( 1 + \frac{4c}{b^2} \right)^{k-1} \binom{2n}{2k-1}. \] (3.8)
6 Summation identities for real numbers representation

The required $Z$-pair $(P, G_{b,c})$ is $P = 1 - (2b^2 + 4c)E_n + 4c^2E_n^2$ and

$$G_{b,c}(n,k) = \left(\frac{1}{2^{n+1}b^2}\right) \left(\frac{b}{2c}\right)^{2n+2} \left(1 + \frac{4c}{b^2}\right)^{k-1} \left( -\frac{(3n-2k+6)b^2}{2k-3} \left(\frac{2n+1}{2k-4}\right) + 2c \left(\frac{2n}{2k-3}\right) \right).$$ (3.9)

**Proof of Theorem 2.3.** Since $\binom{n+k+1}{2k} = 0$ for $k > n + 1$ and $k < 0$, the identity in Theorem 2.3 can be rewritten as

$$\sum_{k \in \mathbb{Z}} b^{2k} \binom{n+k+1}{2k} = \frac{b+1}{b+2} \left[ 1 + \binom{1}{(b+1)^{2n+3}} \right].$$ (3.10)

The $Z$-pair $(P, G_b)$ associated with the summand $F_b(n,k)$ of the left-hand side of (3.10) is

$$P = 1 - (b^2 + 2b + 2)E_n + (b + 1)^2E_n^2, \quad G_b(n,k) = -\frac{b^{2k}}{(b+1)^{n+k+1}} \left(\frac{n+k+1}{2k-2}\right).$$ (3.11)

**Proof of Theorem 2.4.** Since $\binom{2n+1}{2k+1} = 0$ for $k > n$ and $k < 0$, the identity in Theorem 2.4 can be rewritten as

$$\sum_{k \in \mathbb{Z}} b^{2k} \binom{2n+1}{2k+1} = \frac{\sqrt{\alpha} + \sqrt{\beta}}{\sqrt{\alpha \beta}} \left(\frac{\beta^{n+1/2} - \alpha^{n+1/2}}{2}\right).$$ (3.12)

The $Z$-pair $(P, G_{b,c})$ associated with the summand $F_{b,c}(n,k)$ of the left-hand side of (3.12) is

$$P = 1 - (2b^2 + 4c)E_n + 4c^2E_n^2, \quad G_{b,c}(n,k) = \left(\frac{b}{2^{n-1}}\right) \left(\frac{b}{2c}\right)^{2n+3} \left(1 + \frac{4c}{b^2}\right)^{k+1} \left( -\frac{(6n-4k+11)b^2}{8k-4} \left(\frac{2n+2}{2k-2}\right) + 2c \left(\frac{2n+1}{2k-1}\right) \right).$$ (3.13)

**Proof of Theorem 2.5.** Reversing the order of summation, the identity can be rewritten as

$$\sum_{m=2}^{2n} \sum_{k=0}^{\lfloor (m-2)/2 \rfloor} b^m \binom{n+k+1}{m} = \frac{b(n+1)}{b+2} - \frac{(b+1)^2}{(b+2)^2} \left(1 - \frac{1}{(b+1)^{2n+2}} \right).$$ (3.14)

Let us denote the left-hand side of (3.14) by $S_b(n)$ and its summand by $F_b(n,m,k)$, that is,

$$F_b(n,m,k) = \frac{b^m}{(b+1)^{n+k+1}} \binom{n+k+1}{m}. \quad (3.15)$$
Then \(F_b(n, m, k) = F_b(k, m, n)\) and \(F_b(n + 1, m, k) = F_b(n, m, k + 1)\). This implies that

\[
F_b(n + 1, m, k) - F_b(n, m, k) = F_b(n, m, k + 1) - F_b(n, m, k).
\tag{3.16}
\]

Summing both sides of (3.16) with respect to \(k\) and with respect to \(m\), we get

\[
S_b(n + 1) - S_b(n) = \frac{2n}{b + 1} \left(1 - \frac{1}{(b + 1)^{2n + 1}}\right).
\tag{3.17}
\]

But

\[
\sum_{m=2}^{2n+1} \left(\sum_{m=0}^{n+1} \left(\begin{array}{c}
\frac{m}{2} + 1 \\
\frac{m}{m/2 + 1}
\end{array}\right) - \frac{b^m}{(b + 1)^{n+1}} \right) = \frac{1}{(b + 1)^{n+1}} \left(\frac{n+1}{b} - 1 - (n+1)b\right)
\]

\[
= 1 - \frac{1}{(b + 1)^{n+1}} - \frac{(n+1)b}{(b + 1)^{n+1}}.
\tag{3.18}
\]

From (3.17) and (3.18), we get that

\[
S_b(n + 1) - S_b(n) = \frac{b}{b + 2} \left(1 - \frac{1}{(b + 2)^{2n + 1}}\right).
\tag{3.19}
\]
and $S_b(1) = b^2/(b+1)^2$. The right-hand side of (3.14) also satisfies this recurrence relation. Hence

$$S_b(n) = \frac{b(n+1)}{b+2} - \frac{(b+1)^2}{(b+2)^2} \left( 1 - \frac{1}{(b+1)^2n+2} \right) \quad \forall n \in \mathbb{N}.$$ \hspace{1cm} (3.20)

**Remark 3.3.** We would like to mention that the recurrence (3.16) can also be automatically generated by MultiSum [10], a Mathematica package which is available from the website http://www.risc.uni-linz.ac.at/research/combinat/software/.

Mathematical Problems in Engineering

Special Issue on Space Dynamics

Call for Papers

Space dynamics is a very general title that can accommodate a long list of activities. This kind of research started with the study of the motion of the stars and the planets back to the origin of astronomy, and nowadays it has a large list of topics. It is possible to make a division in two main categories: astronomy and astrodynamics. By astronomy, we can relate topics that deal with the motion of the planets, natural satellites, comets, and so forth. Many important topics of research nowadays are related to those subjects. By astrodynamics, we mean topics related to spaceflight dynamics.

It means topics where a satellite, a rocket, or any kind of man-made object is travelling in space governed by the gravitational forces of celestial bodies and/or forces generated by propulsion systems that are available in those objects. Many topics are related to orbit determination, propagation, and orbital maneuvers related to those spacecrafts. Several other topics that are related to this subject are numerical methods, nonlinear dynamics, chaos, and control.

The main objective of this Special Issue is to publish topics that are under study in one of those lines. The idea is to get the most recent researches and published them in a very short time, so we can give a step in order to help scientists and engineers that work in this field to be aware of actual research. All the published papers have to be peer reviewed, but in a fast and accurate way so that the topics are not outdated by the large speed that the information flows nowadays.

Before submission authors should carefully read over the journal's Author Guidelines, which are located at http://www.hindawi.com/journals/mpe/guidelines.html. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:
